# Trough is part of the solar system

#### **Overview**

How does a solar trough work?

These troughs can track the Sun around one axis, typically oriented north-south to ensure the highest possible efficiency. The fluid flows through this tube and absorbs heat from the concentrated solar energy. Similar to a parabolic trough is a linear Fresnel system. These collectors resemble parabolic troughs but use long flat Fresnel mirrors.

What is a parabolic trough solar thermal system?

Since 1985 a solar thermal system using this principle has been in full operation in California in the United States. It is called the SEGS system. Other CSP designs lack this kind of long experience and therefore it can currently be said that the parabolic trough design is the most thoroughly proven CSP technology.

What is a parabolic trough?

A parabolic trough is a type of solar thermal device which is straight in one dimension and curved as a parabola (two-dimensional U-shaped symmetrical curve) in the other two. You might find these chapters and articles relevant to this topic. A parabolic trough is a type of solar thermal energy and is the most developed solar energy technology.

What is a parabolic trough solar concentrator?

The traditional parabolic trough solar concentrator is widely used in the solar collection field, especially in a solar thermal power plant, because it has the most mature technology. Under the condition of accuracy tracking by a precise mechanism, it can achieve heat at a temperature higher than 400°C.

Can a parabolic trough track the Sun?

ystems.3.4.1 Solar field orientationTheoretically, the parabolic troughs in the solar field of a CSP plant can have any orientation. I is always possible to track

the Sun. However, there is a preferred orientation, which is the north-south alignment w.

How is solar irradiance reflected in a parabolic trough?

Solar irradiance falling on the parabolic trough is reflected and focused on an absorber tube. This tube contains a heat-absorbing, fluid-like molten salt mixture or synthetic oil. Heat exchangers are used to transfer the heat from the molten salt to the working fluid, converting it into steam and operating a steam turbine for power generation.
